The p53 tetramerization domain and its mutants

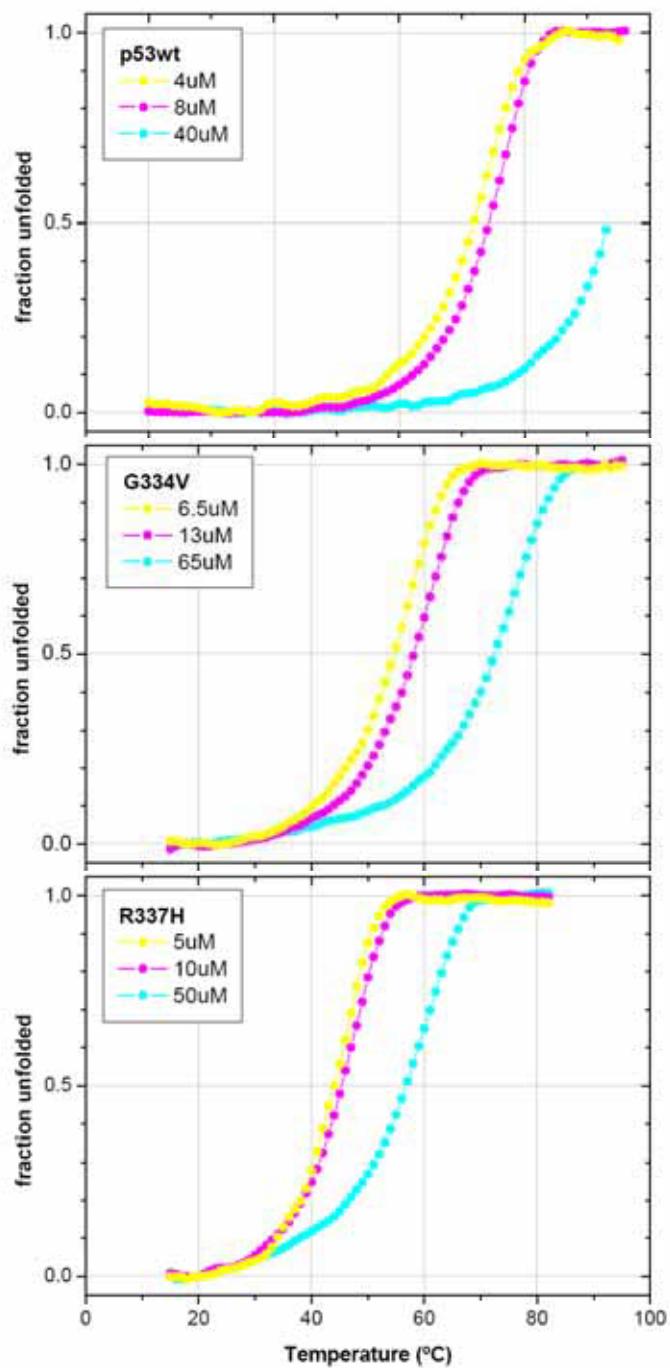

CD unfolding curves: concentration effects

Figure S1. CD unfolding curves in 25mM sodium phosphate buffer pH 7.0, 100mM NaCl, tracing θ at 220nm. Concentrations given as monomer.

G334V precipitation events in CD unfolding curves

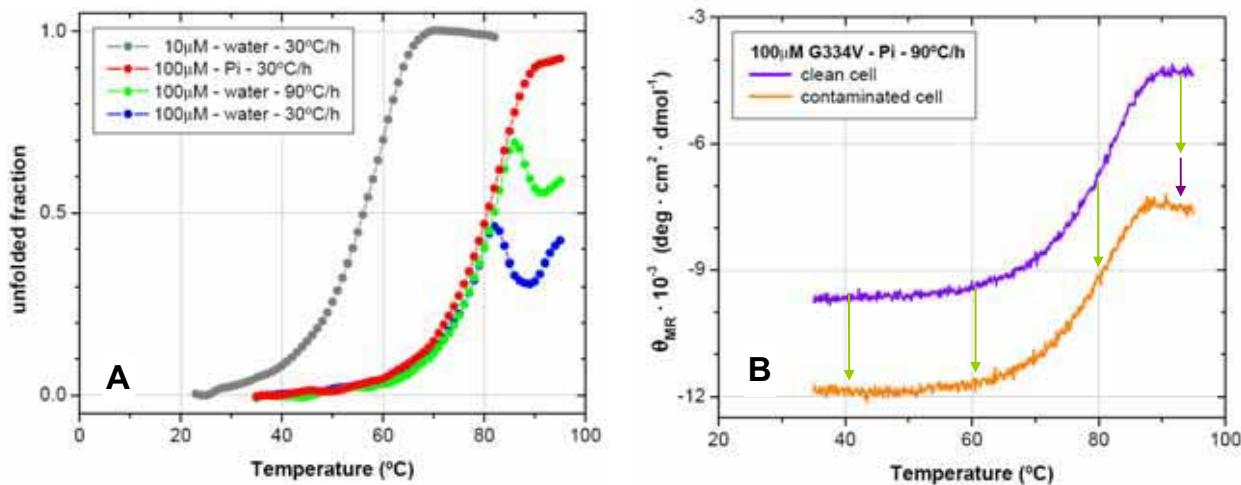

Figure S2. (A) Effects of concentration (10 μM vs. 100 μM monomer), buffer (water vs. 25 mM phosphate, at pH 7) and heating rate (30 vs. 90 °C/h). (B) G334V-aggregates contamination effects: the melting curve in orange was recorded in a cell where G334V had previously precipitated and was not cleaned with chromic mixture; the ellipticity was larger as a result of the protein that had been stuck onto the cell walls (green arrows). Said “contamination” also affected the unfolding pathway of the protein in solution (purple arrow).

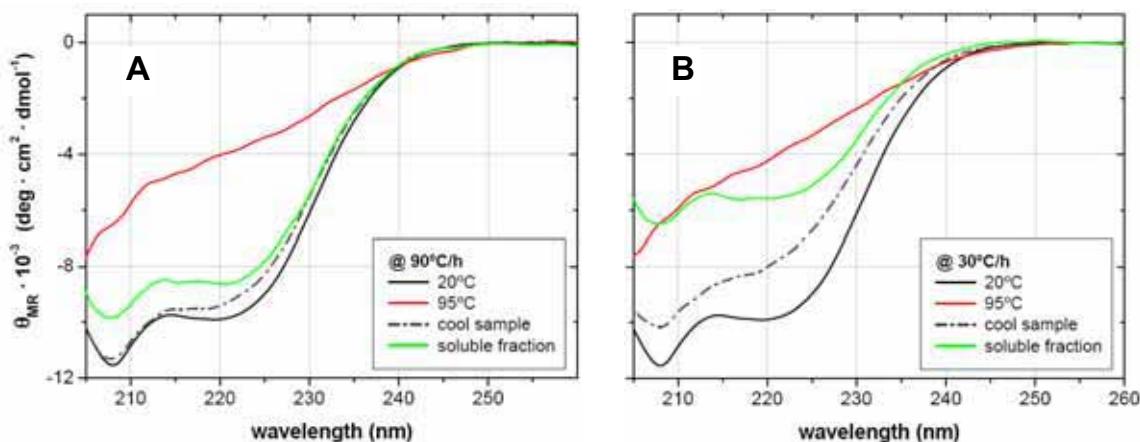

Figure S3. G334V precipitation and stacking onto the cell walls. In black, the CD spectrum for 100 μM G334V (monomer) in water pH 7 at 20°C. In red, the unfolded profile at 95°C, after heating at (A) 90°C/h or (B) 30°C/h. The dashed grey line corresponds to the denatured samples cooled again, in the same cell. The spectrum for the soluble fraction of that sample is in green.

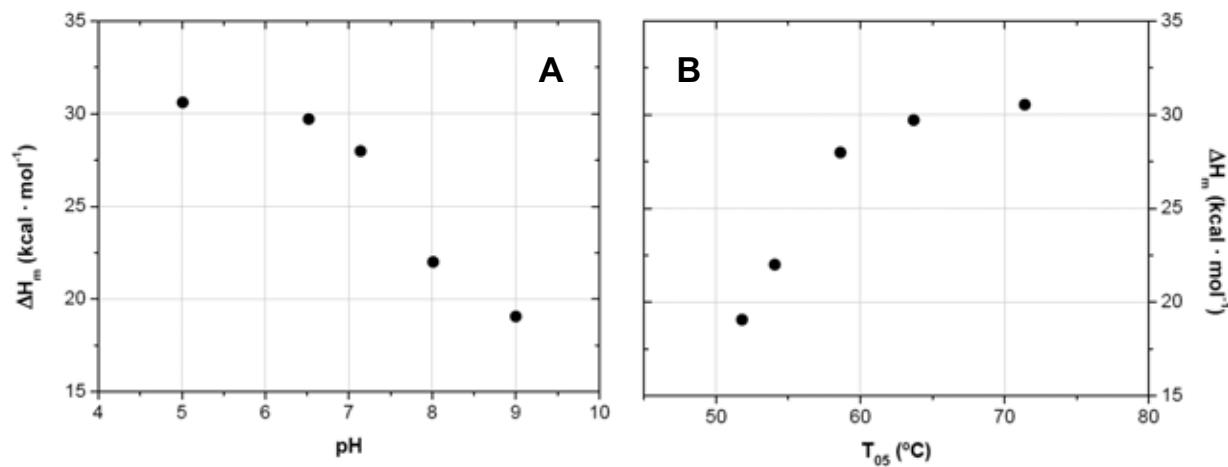

R337H DSC CURVES: effects of pH on ΔH_m 

Figure S4. Melting enthalpy for R337H plotted against (A) the pH and (B) the melting temperature (samples from Figure 1.25, main text).

DSC CURVES. Mathematical adjustment to $N_4 \rightleftharpoons 4U$

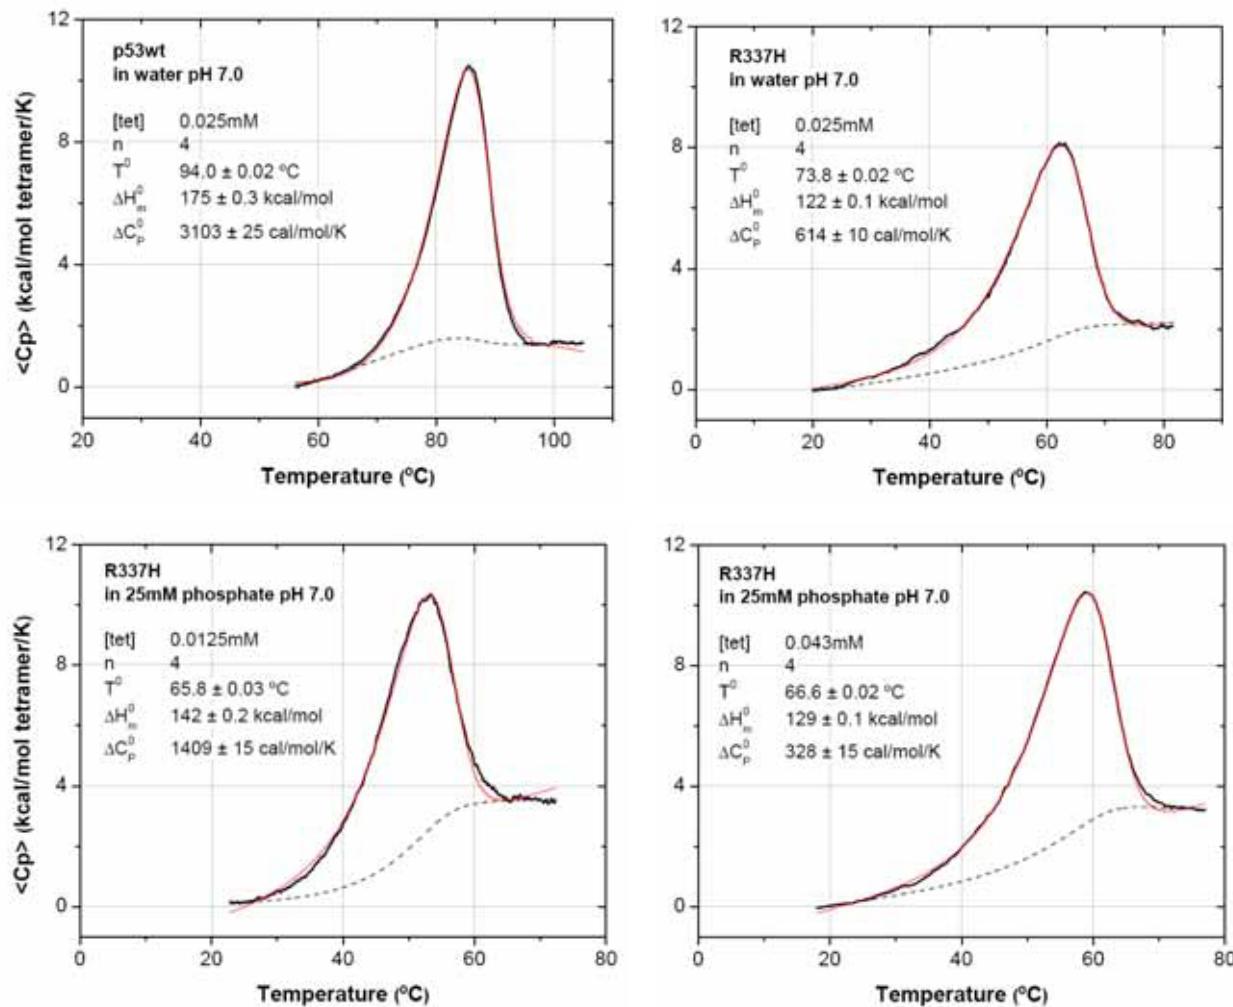

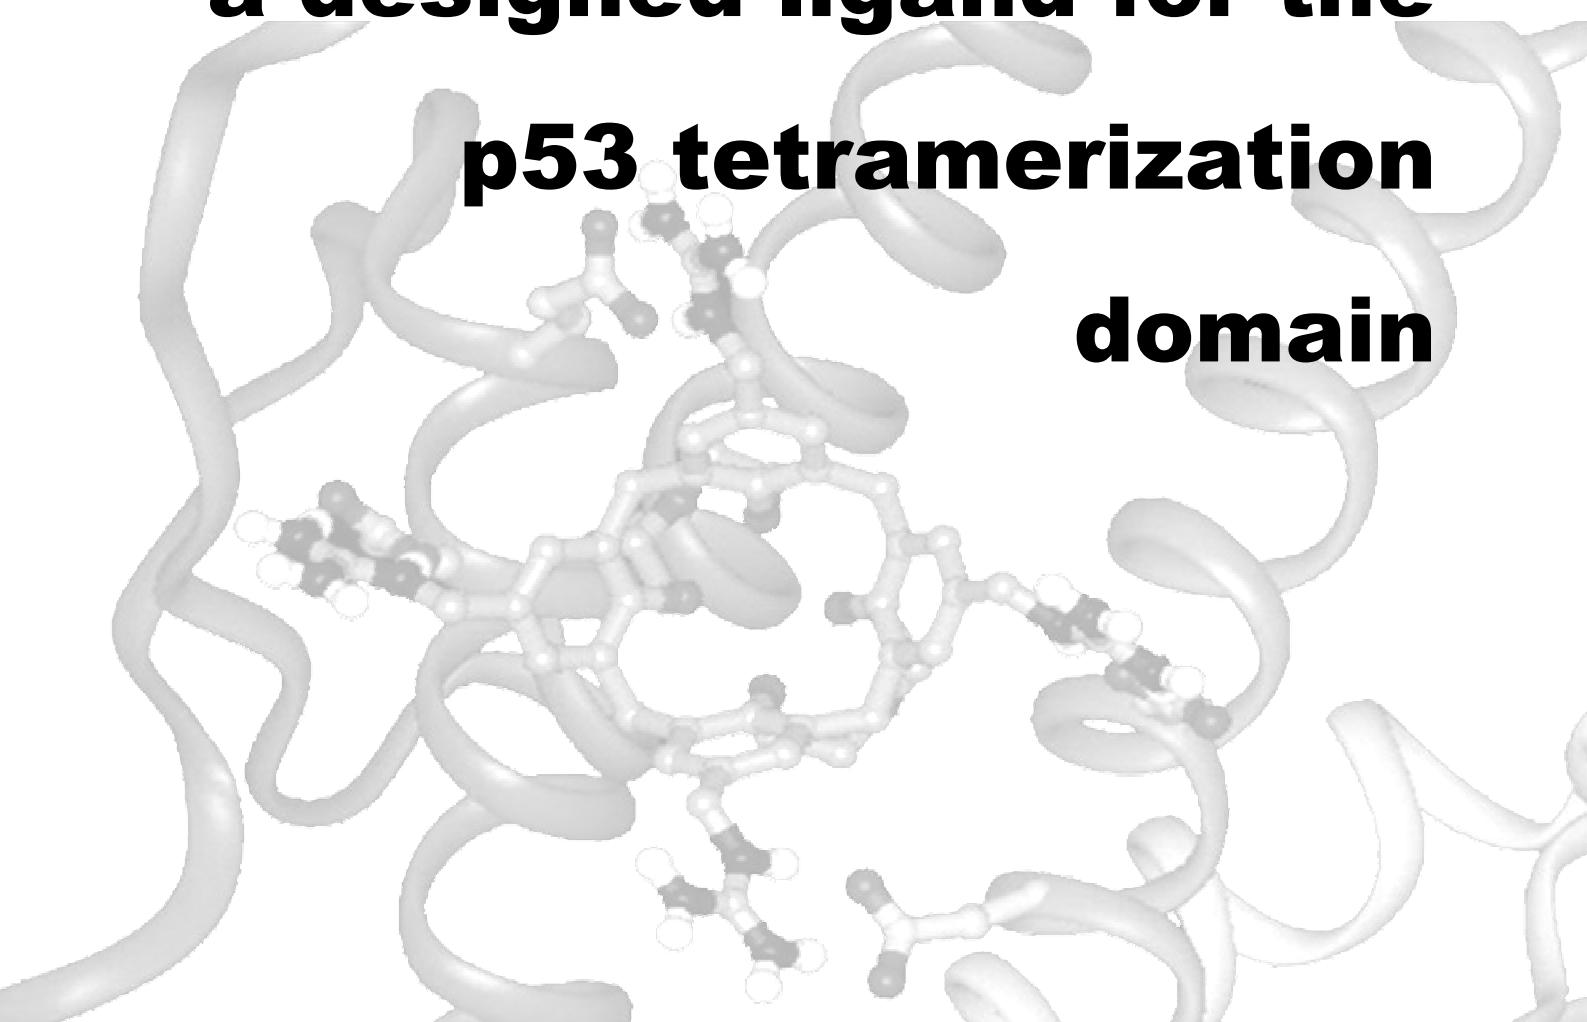

Figure S5. Adjustment to the mathematical model of dissociation coupled to unfolding proposed by Freire *et al.* Values are given related to moles of tetramer.

¹H-STD for NH₂-calix4bridge

In order to confirm that STD results were not experimental artifacts, STD build-up curves were also traced for NH₂-calix4bridge. Its affinity was considerably lower ($K_D \sim 0.8\text{mM}$), but still within the range for STD experiments. Lower temperature and lower ligand excess were used in order to improve the STD signals. Decreasing the ligand excess also decreases the observed STD, but it is balanced by the increase in the signal-to-noise ratio.³²

The quality for the STD experiment on NH₂-calix4bridge was considerably lower than the achieved for calix4bridge, but high enough as to quantify the differences.

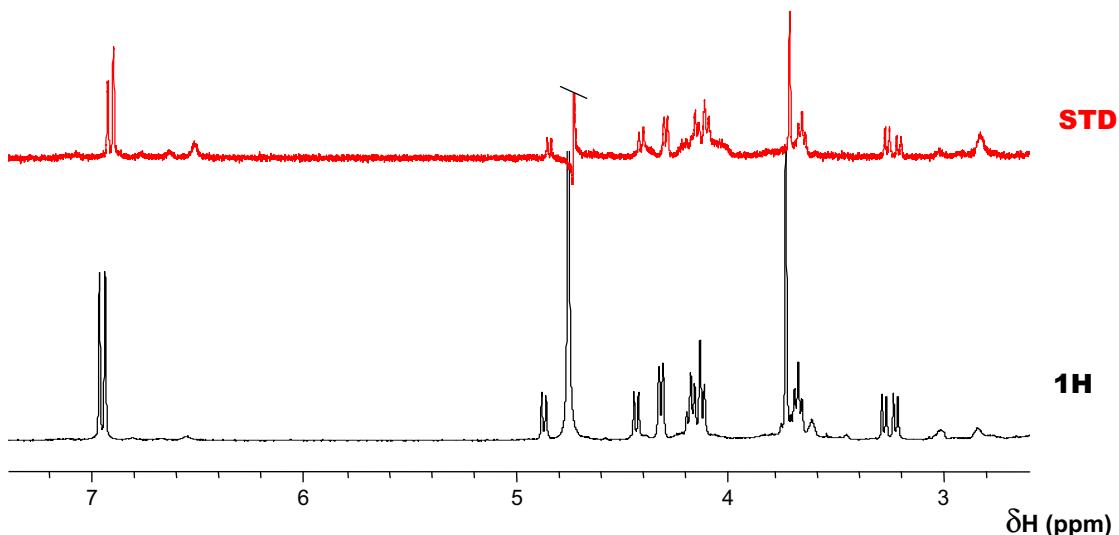

Figure S7. ¹H (black) and ¹H-STD (red) experiments on a 1mM NH₂-calix4bridge sample in the presence of 16.25 μM tetrameric p53wt (600MHz, D₂O, 283K). STD experiment recorded with 1024 scans, using 50ms Gaussian shaped pulses during 3s for saturation at 0.72ppm and a 20ms spinlock.

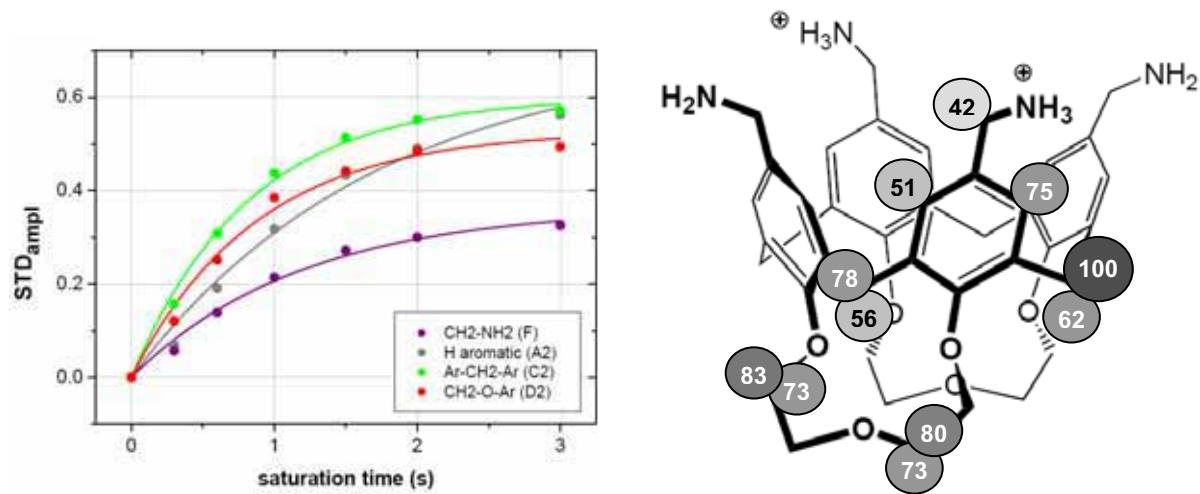

Figure S8. STD build-up curves for NH₂-calix4bridge protons with different T1 and different saturation degrees (1mM ligand, 20μM tetrameric p53wt, 600MHz, D₂O, 283K). STD results are represented on NH₂-calix4bridge molecule (normalized to that of C2).

Table S1. Parameters for the mathematical adjustment of the STD built-up curves and saturation percentages for NH₂-calix4bridge.

^(a) The lower STD_{max} than for calix4bridge indicates of lower affinity.

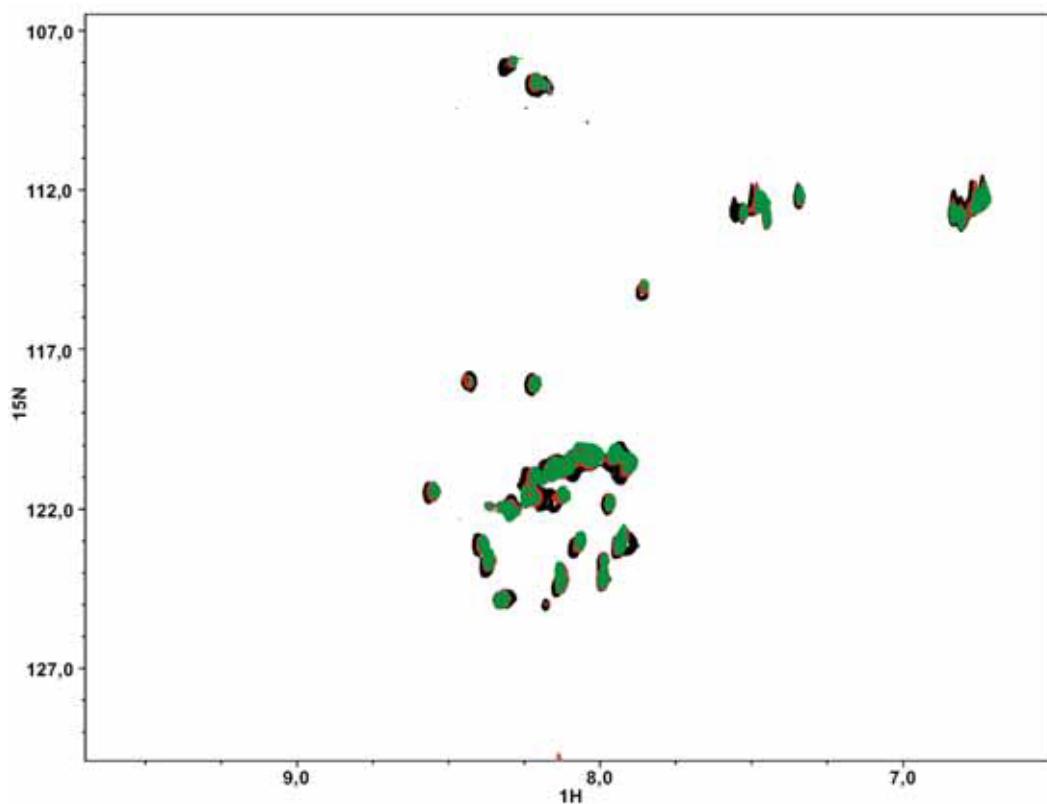

L344P negative control: HSQC

Figure S 9. HSQC spectra of $400\mu\text{M} ^{15}\text{N}$ -L344P in the absence (black) and the presence of 0.8mM (red) and 1.6mM (green) of calix4bridge. Upon addition of the ligand, the protein resonances experienced some minor perturbation, which suggested a non-specific interaction due to the large excess of ligand and the flexibility of the peptide.

L344P negative control: ESI-MS

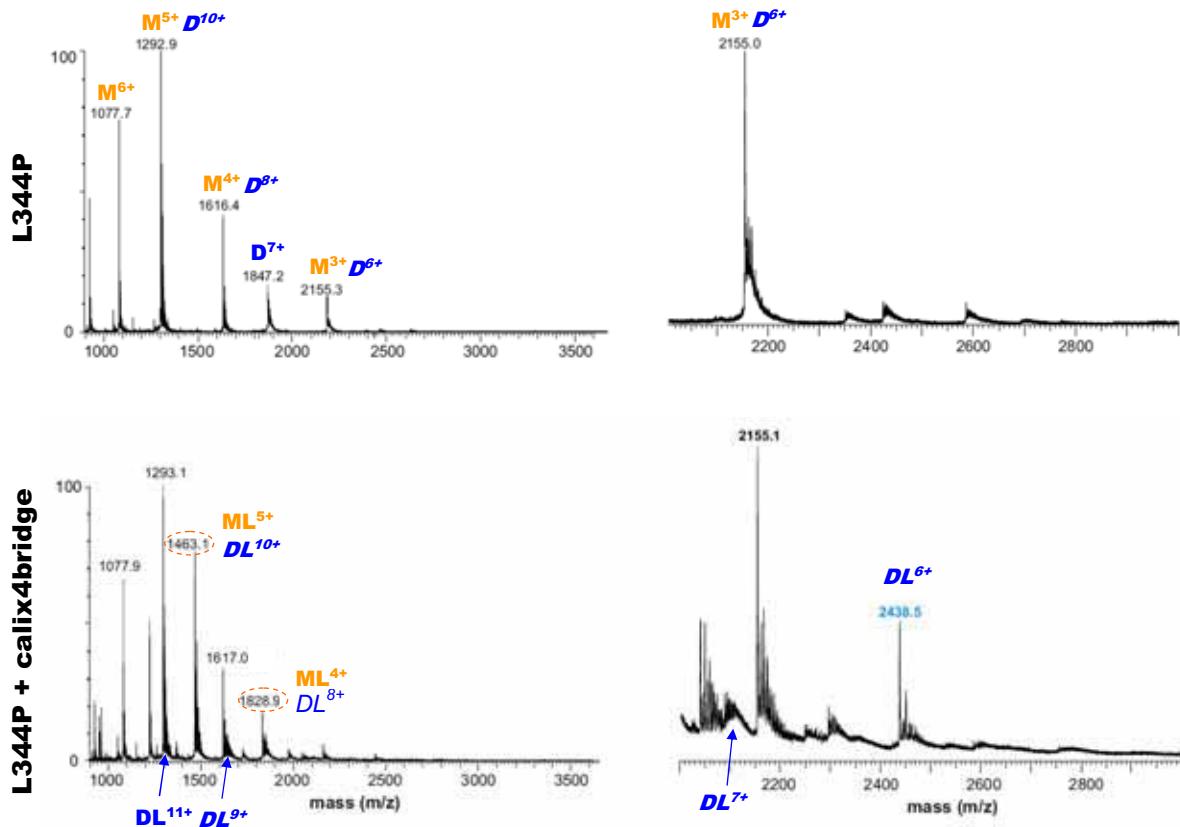

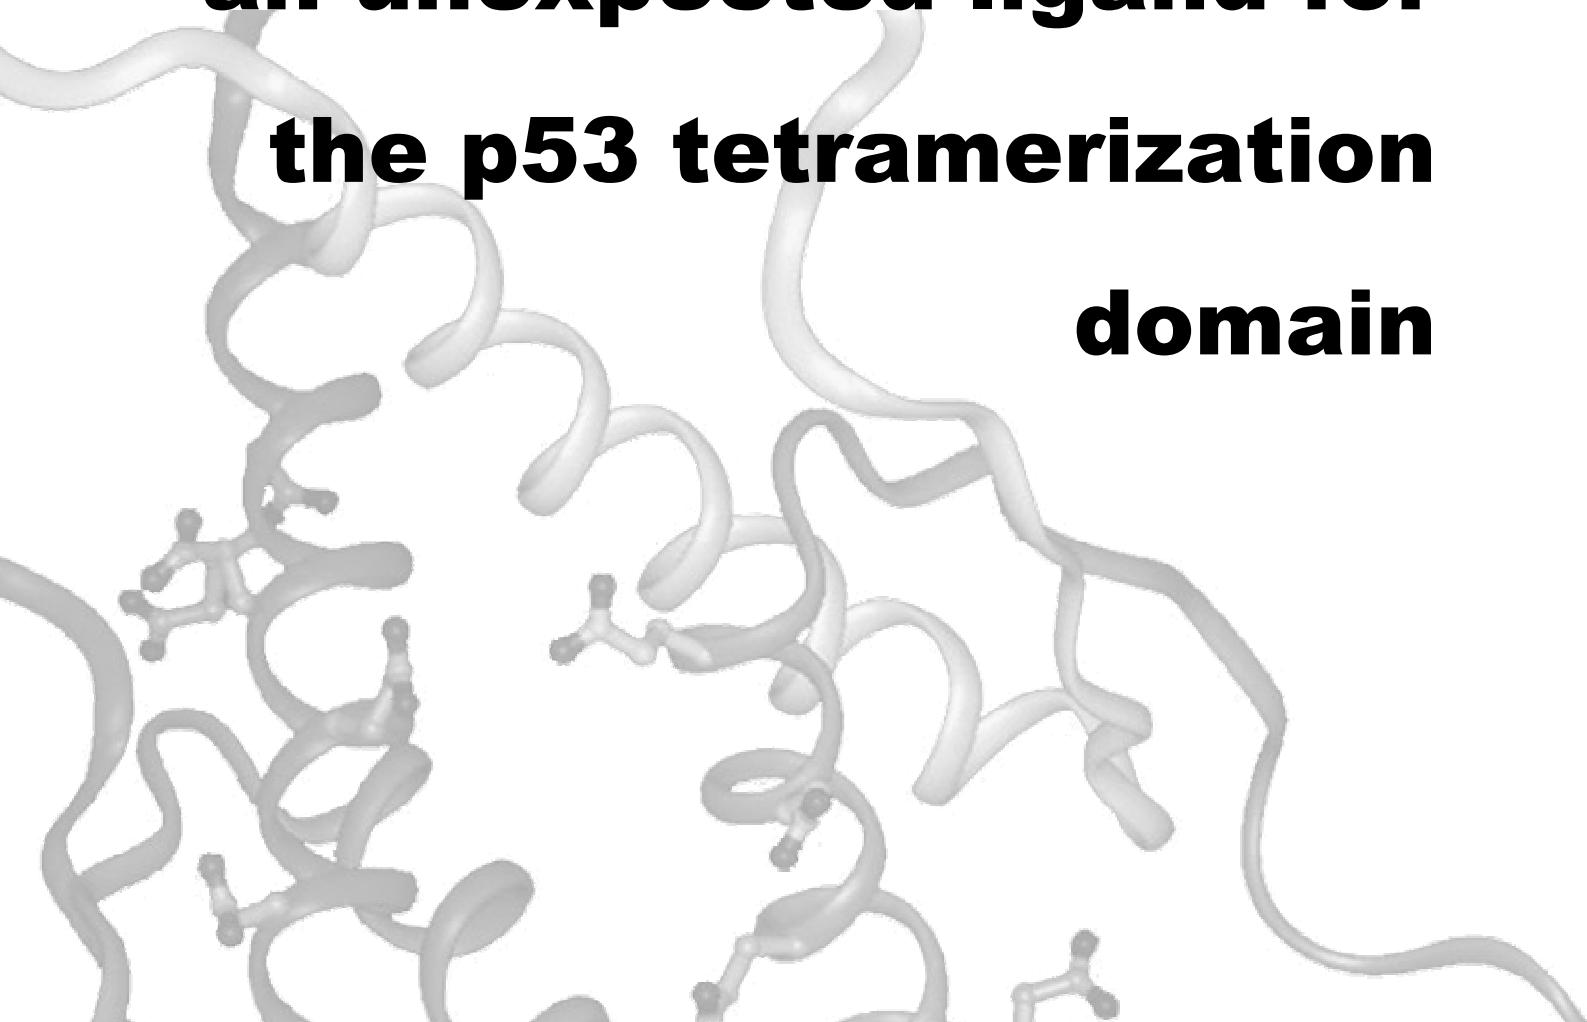

Figure S10. ESI-MS spectra of 50 μM L344P in 10 mM sodium acetate at pH 7, in the absence and the presence of 130 μM calix4bridge (**M**, monomer; **D**, dimer).
